Simplify the network

REDUCE NETWORK COMPLEXITY AND COST by combining security and traffic management into a single-layer, Internet front end, eliminating the need for dedicated devices. *Rainfront* eliminates the need to purchase and replicate separate dedicated devices by consolidating multiple layers of firewalls, load-balancing traffic management devices and other dedicated point solutions into a single, easy-to-manage layer. The creation of this single horizontal layer increases manageability and simplifies the infrastructure architecture. Rainfront is a software-only solution that will run on Windows NT, Solaris and Linux. Based on Rainfinity's core technology, a reliable array of independent nodes (RAIN), Rainfront clusters together any number of Internet front ends. When Rainfront detects any Web server hardware or software failure, it automatically shifts traffic and sessions to the remaining healthy Web servers, without interrupting service or disconnecting any HTTP sessions that were running on the failed Web server. This distributed server-clustering technology alleviates performance and communications bottlenecks, and ensures uninterrupted Internet service. It also allows the infrastructure to grow painlessly and without limit as Internet demands increase.—Rainfinity
